Human infection with avian influenza A (H5) viruses

Human infection with avian influenza A (H5N1) virus
From 25 to 31 March 2016, no new cases of human infection with avian influenza A (H5N1) virus were reported to WHO in the Western Pacific Region.

From February 2003 to 31 March 2016, 238 cases of human infection with avian influenza A (H5N1) virus were reported from four countries within the Western Pacific Region (Table 1). Of these cases, 134 were fatal, resulting in a case fatality rate (CFR) of 56%.

Table 1: Cumulative number laboratory-confirmed human cases (C) and deaths (D) of influenza A (H5N1) virus infection reported to WHO (January 2003 to 25 February 2016), Western Pacific Region.

From February 2003 to 25 February 2016, there have been 846 cases of human infection with avian influenza A (H5N1) virus reported from 16 countries worldwide. Of these cases, 449 were fatal, resulting in a CFR of 53.1%.

Human infection with avian influenza A (H5N6) virus
From 25 to 31 March 2016, no new cases of human infection with avian influenza A (H5N6) virus were reported on the Disease Outbreak News. The last case was reported on 23 March 2016. Since May 2014, a total of ten human cases of influenza A (H5N6) have been reported and all cases were reported from China.

Public health risk assessment for human infection with avian influenza A (H5) viruses
Whenever avian influenza viruses are circulating in poultry, sporadic infections and small clusters of human cases are possible in people exposed to infected poultry or contaminated environments, therefore sporadic human cases would not be unexpected.

With the rapid spread and magnitude of avian influenza outbreaks due to existing and new influenza A (H5) viruses in poultry in areas that have not experienced this disease in animals recently, there is a need for increased vigilance in the animal and public health sectors. Community awareness of the potential dangers for human health is essential to prevent infection in humans. Surveillance should be enhanced to detect human infections if they occur and to detect early changes in transmissibility and infectivity of the viruses.

For more information on confirmed cases of human infection with avian influenza A (H5) virus reported to WHO, visit: [http://www.who.int/influenza/human_animal_interface/en/](http://www.who.int/influenza/human_animal_interface/en/)
Human infection with avian influenza A (H7N9) virus in China

From 25 to 31 March 2016, one (1) new case of human infection with avian influenza A (H7N9) virus from Hong Kong Special Administrative Region was reported on the Disease Outbreak News. The case is an 81-year-old female with underlying illness and recent travel history to Guangdong Province, China. Her date of illness onset was 10 March 2016 and she has a history of exposure to slaughtered poultry. The case was in a stable condition at the time of report. http://www.who.int/csr/don/29-march-2016-avian-ah7n9-china/en/

WHO is continuing to assess the epidemiological situation and will conduct further risk assessments with new information. Overall, the public health risk from avian influenza A (H7N9) viruses has not changed.

Further sporadic human cases of avian influenza A (H7N9) infection are expected in affected and possibly neighbouring areas. Should human cases from affected areas travel internationally, their infection may be detected in another country during or after arrival. If this were to occur, community level spread is considered unlikely as the virus does not have the ability to transmit easily among humans.

Public health risk assessment for avian influenza A (H7N9) viruses

On 23 February 2015, WHO conducted a public health risk assessment for avian influenza A (H7N9). This assessment found the overall public health risk from avian influenza A (H7N9) viruses has not changed since the previous assessment, published on 2 October 2014. To date, there has been no evidence of sustained human-to-human transmission of avian influenza A (H7N9) virus. Human infections with the A(H7N9) virus are unusual and need to be monitored closely in order to identify changes in the virus and/or its transmission behaviour to humans as it may have a serious public health impact.

Animal infection with avian influenza

From 25 to 31 March 2016, there was one new animal outbreak avian influenza virus reported in the Western Pacific Region, an outbreak of (H5N8) in Korea.

HPAI (H5N8) outbreak in poultry in Korea

One new outbreak of HPAI (H5N8) infection in poultry was reported in Gyeonggi-Do, Korea. The outbreak started on 23 March 2016. In total, 20 of 10,907 susceptible birds have died and 10,887 were destroyed during this outbreak.
