Human infection with avian influenza A(H5) viruses

Human infection with avian influenza A(H5N1) virus

From 11 to 17 November 2016, no new cases of human infection with avian influenza A(H5N1) virus were reported to WHO in the Western Pacific Region.

From January 2003 to 17 November 2016, a total of 238 cases of human infection with avian influenza A (H5N1) virus were reported from four countries within the Western Pacific Region (Table 1). Of these cases, 134 were fatal, resulting in a case fatality rate (CFR) of 56%.

Table 1: Cumulative number laboratory-confirmed human cases (C) and deaths (D) of influenza A (H5N1) virus infection reported to WHO (January 2003 to 17 November 2016), Western Pacific Region.

From January 2003 to 17 November 2016, there have been 854 cases of human infection with avian influenza A(H5N1) virus reported from 16 countries worldwide. Of these cases, 450 were fatal, resulting in a CFR of 52.7%.

Human infection with avian influenza A(H5N6) virus

From 11 to 17 November 2016, no new cases of human infection with avian influenza A(H5N6) virus were reported to WHO in the Western Pacific Region. The last case was reported on 30 May 2016 (source: http://www.who.int/csr/don/08-june-2016-ah5n6-china/en/).

Public health risk assessment for human infection with avian influenza A(H5) viruses

Whenever avian influenza viruses are circulating in poultry, sporadic infections and small clusters of human cases are possible in people exposed to infected poultry or contaminated environments, therefore sporadic human cases would not be unexpected.

With the rapid spread and magnitude of avian influenza outbreaks due to existing and new influenza A(H5) viruses in poultry in areas that have not experienced this disease in animals recently, there is a need for increased vigilance in the animal and public health sectors. Community awareness of the potential dangers for human health is essential to prevent infection in humans. Surveillance should be enhanced to detect human infections if they occur and to detect early changes in transmissibility and infectivity of the viruses.

Human infection with avian influenza A (H7N9) virus in China

From 11 to 17 November 2016, there were 2 additional cases of human infection with avian influenza A(H7N9) virus reported to WHO. On 12 November 2016, the National Health and Family Planning Commission (NHFPC) of China notified WHO of 2 additional Laboratory-confirmed cases of Human infection with avian influenza A(H7N9) virus with no death cases. The first case was a 77-year-old female peasant who resides in Huzhou City, Zhejiang Province and purchased poultry at a live poultry market prior to the symptom onset. The other case was an 89-year-old male who resides in Suzhou City, Jiangsu Province, and has no exposure to poultry or live poultry market.

Further sporadic human cases of avian influenza A(H7N9) infection are expected in affected and possibly neighbouring areas. Should human cases from affected areas travel internationally, their infection may be detected in another country during or after arrival. If this were to occur, community level spread is considered unlikely as the virus does not have the ability to transmit easily among humans.

Public health risk assessment for avian influenza A(H7N9) viruses

On 23 February 2015, WHO conducted a public health risk assessment for avian influenza A(H7N9). This assessment found the overall public health risk from avian influenza A(H7N9) viruses has not changed since the previous assessment, published on 2 October 2014. To date, there has been no evidence of sustained human-to-human transmission of avian influenza A(H7N9) virus. Human infections with the A(H7N9) virus are unusual and need to be monitored closely in order to identify changes in the virus and/or its transmission behaviour to humans as it may have a serious public health impact.
