Human infection with avian influenza A(H5) viruses

Human infection with avian influenza A(H5N1) virus
Between 22 and 28 September 2017, no new cases of human infection with avian influenza A(H5N1) virus were reported to WHO in the Western Pacific Region.

As of 28 September 2017, a total of 238 cases of human infection with avian influenza A(H5N1) virus were reported from four countries within the Western Pacific Region since January 2003 (Table 1). Of these cases, 134 were fatal, resulting in a case fatality rate (CFR) of 56%. The last case was reported from China and its onset date was 27 December 2015 (1 case, no death).

Globally, from January 2003 to 14 September 2017, there were 859 cases of human infection with avian influenza A(H5N1) virus reported from 16 countries worldwide. Of these 859 cases, 453 were fatal (CFR of 52.7%). The last case was reported from Egypt on 8 April 2017. (source: [http://www.who.int/influenza/human_animal_interface/H5N1_cumulative_table_archives/en/](http://www.who.int/influenza/human_animal_interface/H5N1_cumulative_table_archives/en/))

Human infection with avian influenza A(H5N6) virus
Between 22 and 28 September 2017, no new cases of human infection with avian influenza A(H5N6) virus were reported to WHO in the Western Pacific Region. The last case was reported on 1 December 2016 (source: [http://www.who.int/csr/don/07-december-2016-ah5n6-china/en/](http://www.who.int/csr/don/07-december-2016-ah5n6-china/en/)). A total of 16 laboratory-confirmed cases of human infection with influenza A(H5N6) virus, including six deaths, have been reported to WHO from China since 2014.

Public health risk assessment for human infection with avian influenza A(H5) viruses
Whenever avian influenza viruses are circulating in poultry, sporadic infections and small clusters of human cases are possible in people exposed to infected poultry or contaminated environments; therefore sporadic human cases are not unexpected.

With continued incidence of avian influenza due to existing and new influenza A(H5) viruses in poultry, there is a need to remain vigilant in the animal and public health sectors. Community awareness of the potential dangers for human health is essential to prevent infection in humans. Surveillance should be continued to detect human cases and early changes in transmissibility and infectivity of the viruses.

For more information on confirmed cases of human infection with avian influenza A (H5) virus reported to WHO, visit: [http://www.who.int/influenza/human_animal_interface/en/](http://www.who.int/influenza/human_animal_interface/en/)

For information on monthly risk assessments on Avian Influenza, visit: [http://www.who.int/influenza/human_animal_interface/HAI_Risk_Assessment/en/](http://www.who.int/influenza/human_animal_interface/HAI_Risk_Assessment/en/)
Human infection with avian influenza A(H7N9) virus in China

Between 22 and 28 September 2017, no new cases of human infection with avian influenza A(H7N9) virus were published in Disease Outbreak News. As of 22 September 2017, a total of 1,562 laboratory-confirmed human infections with avian influenza A(H7N9) virus have been reported to WHO since early 2013 and published in Disease Outbreak News.

Between 15 September and 21 September 2017, China CDC has not reported any additional human cases with highly pathogenic avian influenza (HPAI) A(H7N9) virus, which have mutations in the hemagglutinin gene indicating a change to high pathogenicity in poultry. The total number of human cases with HPAI A(H7N9) virus during 5th wave remains at 28. These 28 cases were from Guangdong, Guangxi, Hebei, Hunan, Shaanxi and Taiwan with illness onset date before July 2017. No increased transmissibility or virulence to human cases has been detected related to the HPAI A(H7N9) virus. (http://www.chinaivdc.cn/cnic/en/Surveillance/WeeklyReport/201708/t20170828_151326.htm).

WHO is continuing to assess the epidemiological situation and will conduct further risk assessments as new information becomes available. The number and geographical distribution of human infections with avian influenza A(H7N9) viruses in the fifth epidemic wave (since October 2016) is greater than previous waves.

Further sporadic human cases of avian influenza A(H7N9) virus infection are expected in affected and possibly neighbouring areas. Should human cases from affected areas travel internationally, their infection may be detected in another country during or after arrival. However, if this were to occur, community level spread is considered unlikely as the virus does not have the ability to transmit easily among humans.

To date, there has been no evidence of sustained human-to-human transmission of avian influenza A(H7N9) virus. Human infections with the A(H7N9) virus are unusual and need to be monitored closely in order to identify changes in the virus and transmission behaviour to humans as this may have serious public health impacts.

Animal infection with avian influenza virus

Between 22 and 28 September 2017, one poultry outbreak of HPAI was reported from the region by OIE: HPAI A(H5N6) in one farm in Viet Nam

HPAI A(H5N6) outbreak in Viet Nam

A new outbreak of HPAI A(H5N6) infection in poultry was reported in Dak Ngoc, Dak Ha, Kon Tum province. The outbreak started on 23 September 2017, and is still ongoing. A total of 500 birds out of 4,700 susceptible birds have died and the remaining 4,200 have been culled as a control measure. http://www.oie.int/wahis_2/public/wahid.php/Diseaseinformation/WI
