Human infection with avian influenza A(H5) viruses

Human infection with avian influenza A(H5N1) virus
Between 22 and 26 December 2017, no new cases of human infection with avian influenza A(H5N1) virus were reported to WHO in the Western Pacific Region.

As of 26 December 2017, a total of 238 cases of human infection with avian influenza A(H5N1) virus were reported from four countries within the Western Pacific Region since January 2003 (Table 1). Of these, 134 were fatal, resulting in a case fatality rate (CFR) of 56%. The last case was reported from China and its onset date was 27 December 2015 (1 case, no death).

Table 1: Cumulative number laboratory-confirmed human cases (C) and deaths (D) of influenza A(H5N1) virus infection reported to WHO, by date of onset (January 2003 to 27 September 2017), Western Pacific Region.

Globally, from January 2003 to 27 September 2017, there were 860 cases of human infection with avian influenza A(H5N1) virus reported from 16 countries worldwide. Of these 860 cases, 454 were fatal (CFR of 52.8%). The last case was reported from Indonesia on 26 September 2017.

Human infection with avian influenza A(H5N6) virus
Between 22 and 26 December 2017, no new cases of human infection with avian influenza A(H5N6) virus were reported to WHO in the Western Pacific Region. The onset date of the last reported case was 7 November 2017. To date, a total of 17 laboratory-confirmed cases of human infection with influenza A(H5N6) virus, including six deaths, have been reported to WHO from China since 2014.

Public health risk assessment for human infection with avian influenza A(H5) viruses
Whenever avian influenza viruses are circulating in poultry, sporadic infections and small clusters of human cases are possible in people exposed to infected poultry or contaminated environments; therefore sporadic human cases are not unexpected.

With continued incidence of avian influenza due to existing and new influenza A(H5) viruses in poultry, there is a need to remain vigilant in the animal and public health sectors. Community awareness of the potential dangers for human health is essential to prevent infection in humans. Surveillance should be continued to detect human cases and early changes in transmissibility and infectivity of the viruses.

For more information on confirmed cases of human infection with avian influenza A(H5) virus reported to WHO, visit: [http://www.who.int/influenza/human_animal_interface/en/](http://www.who.int/influenza/human_animal_interface/en/)

Human infection with avian influenza A(H7N9) virus in China

Between 22 and 26 December 2017, no new cases of human infection with avian influenza A(H7N9) virus were reported to WHO in the Western Pacific Region. The onset date of the last reported case was 21 November 2017. This was the first reported case of the 6th epidemic wave. As of 21 December 2017, a total of 1,565 laboratory-confirmed human infections with avian influenza A(H7N9) virus, including 40 two to three person clusters, have been reported to WHO since early 2013.

Between 22 and 26 December 2017, China CDC has not reported any additional human cases with highly pathogenic avian influenza (HPAI) A(H7N9) virus, which have mutations in the hemagglutinin gene indicating a change to high pathogenicity in poultry. The total number of human cases with HPAI A(H7N9) virus during 5th wave remains at 32. These 32 cases were from Fujian, Guangdong, Guangxi, Hebei, Henan, Hunan, Shaanxi, Taiwan (the case had travel history to Guangdong), and Yunnan. No increased transmissibility or virulence of the virus within human cases has been detected related to the HPAI A(H7N9) virus. (source: http://www.chinaivdc.cn/cnic/en/Surveillance/WeeklyReport/)

WHO is continuing to assess the epidemiological situation and will conduct further risk assessments as new information becomes available. The number and geographical distribution of human infections with avian influenza A(H7N9) viruses in the fifth epidemic wave (since October 2016) is greater than previous waves.

Further sporadic human cases of avian influenza A(H7N9) virus infection are expected in affected and possibly neighbouring areas. Should human cases from affected areas travel internationally, their infection may be detected in another country during or after arrival. However, if this were to occur, community level spread is considered unlikely as the virus does not have the ability to transmit easily among humans.

To date, there has been no evidence of sustained human-to-human transmission of avian influenza A(H7N9) virus. Human infections with the A(H7N9) virus are unusual and need to be monitored closely in order to identify changes in the virus and transmission behaviour to humans as this may have serious public health impacts.

Human infection with avian influenza A(H9N2) in China

Between 22 and 26 December 2017, no new cases of human infection with avian influenza A(H9N2) virus were reported to WHO in the Western Pacific Region. The onset date of the last reported case was 27 November 2017. There have been five human cases of avian influenza A(H9N2) reported from China to WHO in 2017.

Animal infection with avian influenza virus

Between 22 and 26 December 2017, outbreaks in birds with avian influenza virus were reported in Republic of Korea and China.

Highly pathogenic avian influenza A(H5N6) virus infection in poultry in Republic of Korea
On 23 December 2017, an outbreak of avian influenza A(H5N6) at a duck farm of Jeollabuk-Do province, Republic of Korea was notified to OIE. All of the 29,000 susceptible poultry were culled. http://www.oie.int/wahis_2/public/wahid.php/Reviewreport/Review?page_refer=MapFullEventReport&reportid=25500
Highly pathogenic avian influenza A(H5N6) virus infection in poultry in Hong Kong SAR, China
On 25 December 2017, one wild bird case of avian influenza A(H5N6) in Hong Kong SAR, China was notified to OIE. A dead Oriental Magpie Robin was found on 21 December 2017. There are no poultry farms located within three kilometres of where the bird was found.

Low pathogenic avian influenza A(H5N6) virus infection in poultry in Taiwan, China
On 26 December 2017, two outbreaks of avian influenza A(H5N6) at two duck farms in Nantou County in Taiwan, China were notified to OIE. All of the 11,848 susceptible poultry were culled.
